

# Performance Testing

|               |                                                      |
|---------------|------------------------------------------------------|
| Date          | 14 July, 2026                                        |
| Team ID       |                                                      |
| Project Name  | Credit Card Approval Prediction (Flask App — app.py) |
| Maximum Marks | 5 Marks                                              |

## Step 1: Testing Overview

| Field                             | Details                                                                                                                          |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Testing Tool Used                 | Apache JMeter, Postman                                                                                                           |
| Type of Testing                   | Load Testing, Stress Testing                                                                                                     |
| Target Modules                    | Flask routes defined in app.py: / (application form), /predict (scoring API), /dashboard, /api/metrics, /sandbox, /notifications |
| Test Environment                  | Local System (Windows 11, Python 3.11, Flask dev server, app.run(host="0.0.0.0", port=7860, debug=True))                         |
| Model Artifacts Loaded at Startup | best_model.joblib, scaler.joblib, feature_columns.joblib, shap_background.joblib (loaded once — not per-request)                 |
| Test Date                         | 14 July, 2026                                                                                                                    |

## Step 2: Test Scenarios

| S.No | Test Scenario / Description                        | Route    | No. of Virtual Users | Duration (sec) | Expected Outcome                                                                        |
|------|----------------------------------------------------|----------|----------------------|----------------|-----------------------------------------------------------------------------------------|
| 1    | Single user submits a credit card application form | /predict | 1                    | 30             | Decision (Approve/Decline), probability and SHAP explanation generated within 2 seconds |
| 2    | Continuous prediction requests from analysts       | /predict | 100                  | 120            | Stable response time, no crashes, correct borderline-band flags (0.40–0.60) queued      |

| 3    | Peak load testing on the scoring API                                                                     | /predict                 | 200                  | 180            | Application remains responsive and maintains acceptable performance under concurrency           |
|------|----------------------------------------------------------------------------------------------------------|--------------------------|----------------------|----------------|-------------------------------------------------------------------------------------------------|
| S.No | Test Scenario / Description                                                                              | Route                    | No. of Virtual Users | Duration (sec) | Expected Outcome                                                                                |
| 4    | Compliance officer/analyst repeatedly loads the dashboard (model comparison + income-vs-approval charts) | /dashboard, /api/metrics | 50                   | 90             | Charts render correctly; /api/metrics recomputes income bins from applicants.csv without errors |
| 5    | Customer explores what-if scenarios in the sandbox                                                       | /sandbox                 | 50                   | 90             | Repeated scoring calls stay fast; nothing is persisted to disk or the notification queue        |
| 6    | Analyst reviews the borderline-case notification queue while /predict is under load                      | /notifications           | 20                   | 60             | In-memory NOTIFICATIONS list renders consistently with no lost or duplicated entries            |

### Step 3: Performance Test Results

| S.No | Metric                                         | Target Value | Actual Value | Status (Pass/Fail) | Remarks                                                                 |
|------|------------------------------------------------|--------------|--------------|--------------------|-------------------------------------------------------------------------|
| 1    | Response Time (Avg) — /predict                 | < 2 seconds  | 1.35 sec     | Pass               | SHAP explanation adds modest overhead vs. a bare model call             |
| 2    | Response Time (Max) — /predict                 | < 5 seconds  | 3.94 sec     | Pass               | Max seen on first request after startup (model already warm, no reload) |
| 3    | Throughput (Req/sec) — /predict                | > 40 req/sec | 48 req/sec   | Pass               | Slightly lower than a plain classifier due to explain() step            |
| 4    | Response Time (Avg) — /dashboard, /api/metrics | < 2 seconds  | 1.62 sec     | Pass               | pandas.cut/groupby over applicants.csv on every call adds latency       |

|   |                         |       |     |      |                                                                              |
|---|-------------------------|-------|-----|------|------------------------------------------------------------------------------|
| 5 | Error Rate (all routes) | < 1%  | 0%  | Pass | No request failures observed                                                 |
| 6 | CPU Utilization         | < 80% | 66% | Pass | Efficient CPU usage under peak load                                          |
| 7 | Memory Utilization      | < 80% | 59% | Pass | Stable; no leak from the in-memory NOTIFICATIONS list during the test window |

## Step 4: Observations & Analysis

### Key Findings

- The Credit Card Approval Prediction Flask app (app.py) successfully processed concurrent requests across /predict, /dashboard, /api/metrics, /sandbox and /notifications.
- Average /predict response time stayed below the 2-second target even with SHAP-based explanations enabled (falls back to global feature\_importance from metrics.json if shap or shap\_background.joblib is unavailable).
- No failed requests were observed; the borderline band ( $0.40 \leq \text{high\_risk\_probability} \leq 0.60$ ) correctly appended entries to the in-memory NOTIFICATIONS list.
- The app remained stable under moderate and heavy workloads on the Flask development server.

### Bottlenecks Identified

- Minor response-time increase beyond 200 concurrent users on /predict, mainly attributable to the shap.Explainer.call inside explain().
- /api/metrics recomputes income-vs-approval bins from data/applicants.csv on every request instead of caching the result, adding avoidable latency under repeated dashboard refreshes.
- The NOTIFICATIONS list is a process-local Python list with no size cap or persistence, so it resets on restart and would need a real datastore for multi-worker deployments.
- app.run(..., debug=True) is fine for local testing but is not representative of production performance; results should be re-validated behind a production WSGI server (e.g. gunicorn).

### Optimization Steps Taken / Recommended

- Model, scaler, feature\_columns and the SHAP background/explainer are all loaded once at import time rather than per-request.
- Reduced unnecessary preprocessing by building the one-hot feature row directly with build\_feature\_row() instead of re-fitting encoders at request time.
- explain() gracefully falls back to precomputed feature\_importance from metrics.json if the SHAP explainer fails, avoiding request failures.
- Recommended follow-up: cache /api/metrics results (e.g. short TTL) and move NOTIFICATIONS to a real database or queue before scaling beyond a single worker.

## Step 5: Screenshots / Evidence

### Model comparison

| Model               | Accuracy | Precision | Recall | F1     | ROC-AUC |
|---------------------|----------|-----------|--------|--------|---------|
| Decision Tree       | 0.73     | 0.9788    | 0.7313 | 0.8372 | 0.7807  |
| Logistic Regression | 0.7633   | 0.9852    | 0.7621 | 0.8594 | 0.8645  |
| Random Forest       | 0.8592   | 0.9774    | 0.8718 | 0.9216 | 0.8611  |
| XGBoost             | 0.9508   | 0.9569    | 0.993  | 0.9746 | 0.8403  |

### Approval rate by income band
